

Prescription Reader — Component Diagram (C4 level 3)

How a photographed pharmacy label becomes an approved medication — and where the local model and the six deterministic guardrails actually sit.

The model proposes; it never decides

qwen2.5:7b is asked only for what the label says — name, strength, frequency, and clock times printed on the label. Reminder times are computed after it, by G4 from a fixed table, so the model cannot put a time on your schedule.

One safety layer, two proposers

If the sidcar or Ollama cannot be reached, the regex proposer takes over. Both paths land in the same guard set, so a fallback changes which proposer spoke — never which rules were applied.

Nothing on this page leaves our network

No arrow here reaches a cloud service: the photo, the text recognition and the model all run on hardware we own. MyPillSafe's one cloud brain, the answer voice, is not on this path.
